Ekman Dynamics

I

Wind Stress

- Wind blowing over the sea surface produces a force per unit area called the **wind stress**.
- The effects of the wind stress are transmitted down into the water column by the action of turbulent eddies generated by breaking waves and boundary shear stresses.

- Let's consider a 2D example, with wind in the x-direction at the ocean surface.
- Horizontal momentum is transferred in the vertical direction.
- For small dz , the stress is proportional to the velocity difference between $z+dz$ and $z+dz/2$:

$$\tau_{xz} = A_z \frac{\partial u}{\partial z}$$

where A_z is the "eddy viscosity".

Ekman Layer Thickness

- The Ekman equations are a balance between rotation and friction:

- Taking: $\frac{\partial^2}{\partial z^2}(1) \Rightarrow (2)$
we eliminate \tilde{v} and:

$$\frac{D^4 \tilde{u}}{Dz^4} + \frac{f^2}{A_V^2} \tilde{u} = 0$$

- The solution of this equation is given by:

$$\tilde{u} = C_1 e^{(1+i)z/\delta_E} + C_2 e^{(1-i)z/\delta_E} + C_3 e^{-(1+i)z/\delta_E} + C_4 e^{-(1-i)z/\delta_E}$$

where

$$\delta_E = \sqrt{\frac{A_V}{|f|/2}}$$

is the **Ekman layer thickness**

- Note that the Ekman layer doesn't depend on U. It depends only on $f^{1/2}$ and $A_V^{1/2}$. The idealized turbulent eddy viscosity coefficient A_V , used instead of molecular viscosity, is assumed to be constant with depth although variants on this have been proposed.

$$-f \tilde{v} = A_V \frac{\partial^2 \tilde{u}}{\partial z^2} \quad (1)$$

$$f(\tilde{u} + U) = A_V \frac{\partial^2 \tilde{v}}{\partial z^2} \quad (2)$$

Ekman Equations

Ekman Spiral

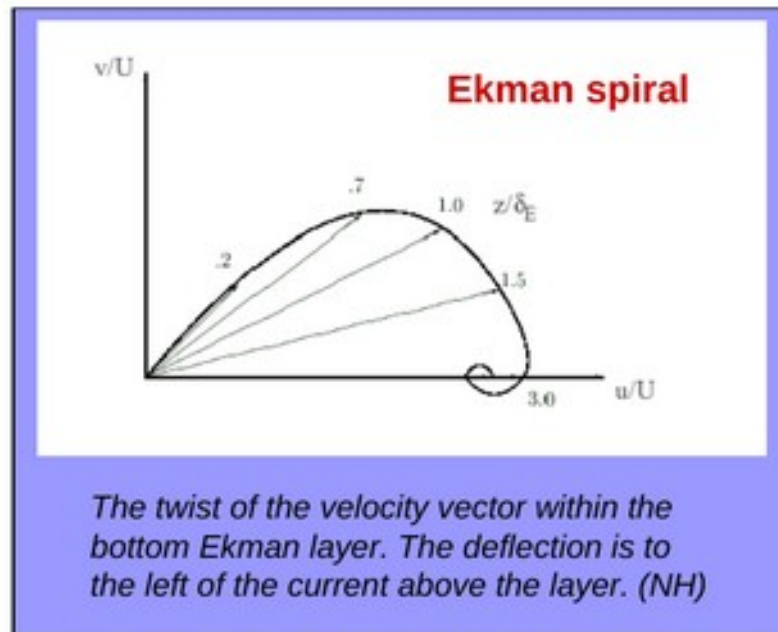

- Due to the appearance of the velocity in the y-direction, the velocity vector changes direction within the Ekman layer.
- As each layer of fluid is frictionally retarded by the layer beneath it, the response of the velocity of the upper layer, due to the planetary rotation, is to turn slowly, producing a spiral as z decreases to zero.

- Fig. represents the vectors projected onto the bottom plane. Numbers indicate the relative distance from the plane to the bottom.

- As the bottom approaches, $z \rightarrow 0$, and from $u = U[1 - e^{-z/\delta_E} \cos(z/\delta_E)]$ it follows: $v = Ue^{-z/\delta_E} \sin(z/\delta_E)$

$$\lim_{z \rightarrow 0} \frac{v}{u} = 1$$

- So, the velocity vector has turned 45° to the left of the geostrophic vel.

Ekman Transport

- The mass transport per unity of area in the Ekman layer is calculated by:

$$M_x = \int_0^{\infty} \bar{u} dz = -\int_0^{\infty} U e^{-z/\delta_E} \cos(z/\delta_E) dz = -U \frac{\delta_E}{2} \quad \Rightarrow \quad \mathbf{M} = \delta_E \frac{U}{2} (-\mathbf{i} + \mathbf{j})$$
$$M_y = U \frac{\delta_E}{2}$$

- The stress exerted by the rigid surface at $z = 0$ is:

$$\tau = -\rho A_V \left(\mathbf{i} \frac{\partial u}{\partial z} \Big|_{z=0} + \mathbf{j} \frac{\partial v}{\partial z} \Big|_{z=0} \right) = -\frac{A_V}{\delta_E} \rho U (\mathbf{i} + \mathbf{j}).$$

- Taking the vectorial product between the stress τ and the unit vector in the z-direction:

$$\tau \times \mathbf{k} = \tau_y \mathbf{i} - \tau_x \mathbf{j} = \frac{A_V \rho U}{\delta_E} (-\mathbf{i} + \mathbf{j}).$$

- Multiplying the above term by δ_E / δ_E , we have: $\tau \times \mathbf{k} = \frac{A_V \rho U \delta_E}{2A_V / f} (-\mathbf{i} + \mathbf{j})$

which gives: $\mathbf{M}_E = \frac{\tau \times \mathbf{k}}{\rho f}$

This means that the **Ekman transport** is **90°** to the **right** of the **frictional stress (NH)**

Ekman Surface Layer

- Using the boundary conditions:

- (1) at the surface ($z = 0$):

$$\tau_{zx} = -\rho A_V \frac{\partial \tilde{u}}{\partial z} \Big|_{z=0}$$

$$\tau_{zy} = -\rho A_V \frac{\partial \tilde{v}}{\partial z} \Big|_{z=0}$$

- (2) Below the Ekman layer ($z \rightarrow -\infty$):

$$\tilde{u}(z \rightarrow -\infty) \rightarrow 0$$

$$\tilde{v}(z \rightarrow -\infty) \rightarrow 0$$

- Then $A_2 = A_4 = 0$ and $A_3 = i A_1$, with

$$A_1 = \frac{\tau_{zx} \delta_E}{2\rho A_V} \left(\frac{1-i}{2} \right)$$

- So, substituting the constants back to the solution, we have:

$$\tilde{u}(z) = \frac{\tau_{zx} \delta_E}{\sqrt{2\rho A_V}} e^{z/\delta_E} \sin\left(\frac{z}{\delta_E} + \frac{\pi}{4}\right)$$

$$\tilde{v}(z) = -\frac{\tau_{zx} \delta_E}{\sqrt{2\rho A_V}} e^{z/\delta_E} \sin\left(\frac{z}{\delta_E} + \frac{\pi}{4}\right)$$

So, at the surface

surface current at 45° to the right (NH)

$$\tilde{u}(z=0) = \frac{\sqrt{2}}{2} V_0$$

$$\tilde{v}(z=0) = -\frac{\sqrt{2}}{2} V_0$$

where $V_0 = \sqrt{u^2|_{z=0} + v^2|_{z=0}} = \frac{\tau_{zx} \delta_E}{\sqrt{2\rho A_V}} = \frac{\tau_{zx}}{\rho \sqrt{f A_V}}$

Ekman Transport

- Similarly to the Ekman bottom layer, we can also calculate the integrated transport in the surface layer:

$$\mathbf{M} = \frac{\boldsymbol{\tau} \times \mathbf{k}}{\rho f}$$

Ekman transport is 90° to the right of the wind stress in the Northern Hemisphere
left of the wind stress in the Southern Hemisphere

Questions:

- Given a typical eddy viscosity coefficient is of order $10^{-2} \text{ m}^2 \text{ s}^{-1}$, and f is $\sim 10^{-4} \text{ s}^{-1}$,
 1. Then what is the order of magnitude of Ekman layer?
 2. How strong is the surface current produced by a wind stress of 0.1 Pa ?

$$\delta_E = \sqrt{\frac{A_v}{|f|/2}}$$

$$V_0 = \frac{\tau_{zx}}{\rho \sqrt{f A_v}}$$

Ekman Summary (so far)

Ekman layer depth: $\delta_E = \sqrt{\frac{A_V}{|f|/2}}$

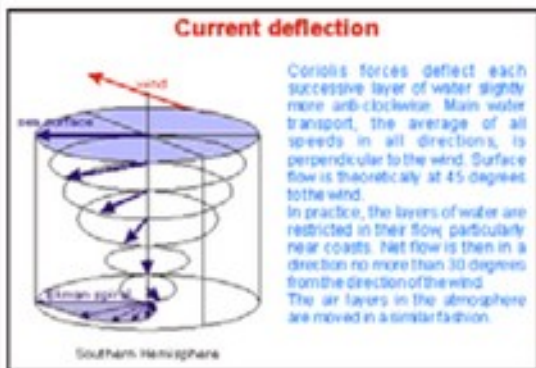

Ekman transport:
90° to the right (left) in the NH (SH)

$$\mathbf{M} = \frac{\boldsymbol{\tau} \times \mathbf{k}}{\rho f}$$

Surface Current:
45° to the right (left) in the NH (SH)

$$\begin{aligned} \bar{u}(z=0) &= \frac{\sqrt{2}}{2} V_0 \\ \bar{v}(z=0) &= -\frac{\sqrt{2}}{2} V_0 \end{aligned}$$

$$V_0 = \frac{\tau_{zx}}{\rho \sqrt{f A_V}}$$

Global Wind Pattern

In the globe we have 3 major wind systems in each hemisphere:
Polar easterlies, mid-latitude westerlies
and the trade winds (easterlies)

- Look at the direction of the winds below and answer what happens to the Ekman transport?

- What happens to this convergence (divergence)?

Ekman Pumping

- Integrating the continuity equation from the bottom to the top of the Ekman surface layer, we have:
$$\frac{\partial M_x}{\partial x} + \frac{\partial M_y}{\partial y} = w_0 - w_E$$

where w_0 is the vertical velocity at the ocean surface and w_E is the vertical velocity at the bottom of the Ekman layer.

- But w_0 is negligible compared to w_E . Using the relations between M and τ , we define the **Ekman pumping velocity**:

$$w_E = \mathbf{k} \cdot \nabla \times \frac{\boldsymbol{\tau}}{f}$$

- This is a very important property of Ekman dynamics because it allow us to know what happen with a flow that convergences or divergence in the ocean.
- This relation says that a **clockwise** wind pattern (**negative curl**) in the Northern Hemisphere generates **downwelling**, whereas a **counterclockwise** wind pattern causes **upwelling**. The directions are opposite in the Southern Hemisphere.

Ekman Pumping

- Consider the stress field in the x -direction, but varying in intensity in the y -direction.
- The Ekman transport is to the right of the applied wind stress.

- Because the wind stress intensity is varying, the transport also varies and causes convergence and divergence in certain regions.
- To conserve mass, fluid is sucked into the Ekman layer at a rate proportional to the divergence of the Ekman flux ($w_E > 0$).
- The inverse occurs in the convergence regions.
- So, there is a net movement of water away from equator. As a consequence, there is a positive Ekman pumping that causes upwelling in the equator.

Ekman Pumping

- In the subtropics, where midlatitude westerlies and the trades coalesce, the net transport generates convergence (subtropical gyres). It generates an upward bulge in the sea surface (and a downward depression of the thermocline).
- These bulges are very slight, i.e. changes of order $O(1\text{m})$ over distances of 100's of km.

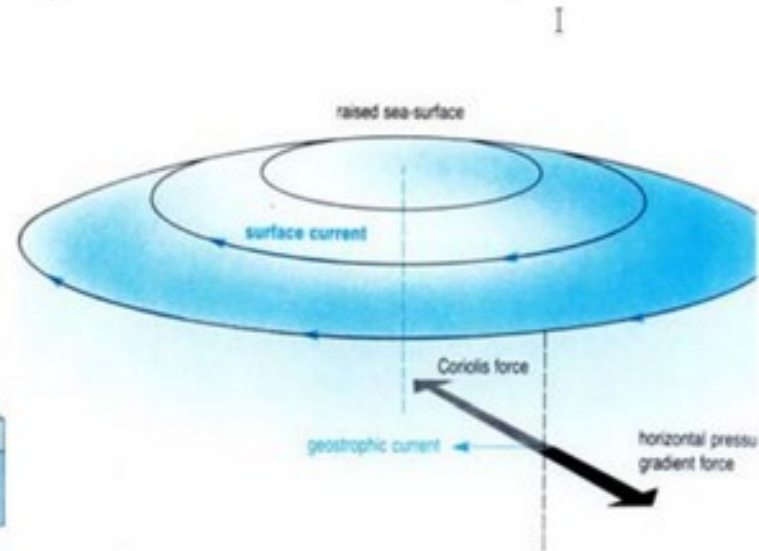

Fig.5 Currents flow (V) around a gyre when the inward Ekman transport due to the Coriolis effect (F_c) is balanced by F_g , the outward force due to gravity.

The generation of geostrophic current flow in a gyre driven by anticyclonic winds in the Northern Hemisphere. This current is driven by the wind only indirectly and persists below the wind-driven (Ekman) layer.

Coastal Upwelling Revisited: Ekman, Bakun, and Improved Upwelling Indices for the U.S. West Coast

Michael G. Jacox^{1,2} , Christopher A. Edwards³ , Elliott L. Hazen¹ , and Steven J. Bograd¹ 

¹NOAA Southwest Fisheries Science Center, Monterey, CA, USA, ²NOAA Earth System Research Laboratory, Boulder, CO, USA, ³University of California, Santa Cruz, CA, USA

Abstract Coastal upwelling is responsible for thriving marine ecosystems and fisheries that are disproportionately productive relative to their surface area, particularly in the world's major eastern boundary upwelling systems. Along oceanic eastern boundaries, equatorward wind stress and the Earth's rotation combine to drive a near-surface layer of water offshore, a process called *Ekman transport*. Similarly, positive wind stress curl drives divergence in the surface Ekman layer and consequently upwelling from below, a process known as *Ekman suction*. In both cases, displaced water is replaced by upwelling of relatively nutrient-rich water from below, which stimulates the growth of microscopic phytoplankton that form the base of the marine food web. Ekman theory is foundational and underlies the calculation of upwelling indices such as the "Bakun Index" that are ubiquitous in eastern boundary upwelling system studies. While generally valuable first-order descriptions, these indices and their underlying theory provide an incomplete picture of coastal upwelling. Here we review the relevant dynamics and limitations of classical upwelling indices, particularly related to representation of the surface wind stress, the influence of geostrophic currents, and the properties of upwelled water. To address these shortcomings, we present two new upwelling indices for the U.S. West Coast (31–47°N), which are available from 1988 to present. The Coastal Upwelling Transport Index and the Biologically Effective Upwelling Transport Index provide improved estimates of vertical transport and vertical nitrate flux, respectively, by leveraging technological and scientific advances realized since the introduction of the Bakun Index nearly a half century ago.

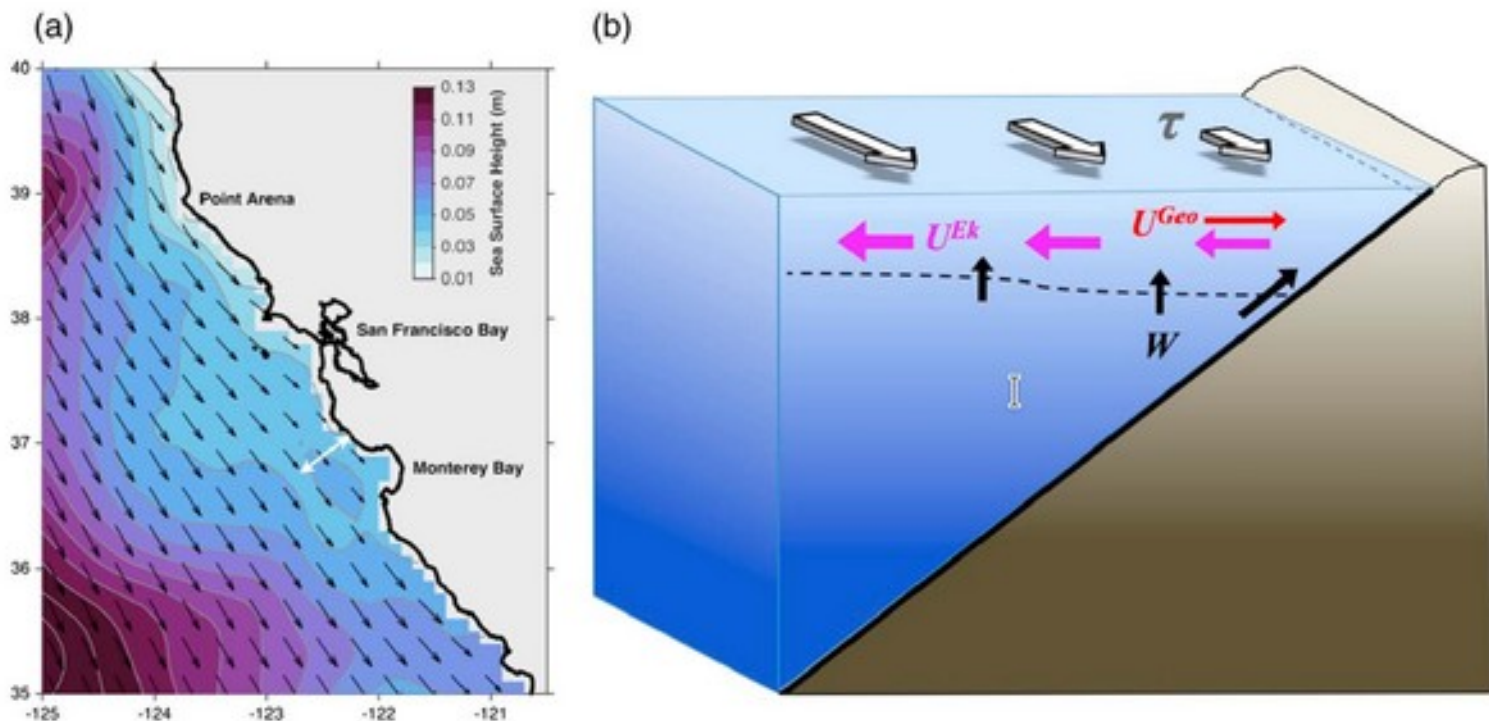

Figure 1. (a) Mean 1988–2017 sea surface height (in color) and wind stress (arrows) during the upwelling season (March–August) off the central/northern California coast, obtained from the California Current System Regional Ocean Modeling System reanalyses; (b) schematic representation of a coastal section corresponding to the white line in (a), showing key components of the upwelling dynamics of central importance to this paper: Alongshore wind stress (τ), an alongshore sea surface height gradient, Ekman transport (U^{Ek}), geostrophic transport (U^{Geo}), vertical transport (W), and the depth of the surface mixed layer (dashed line).

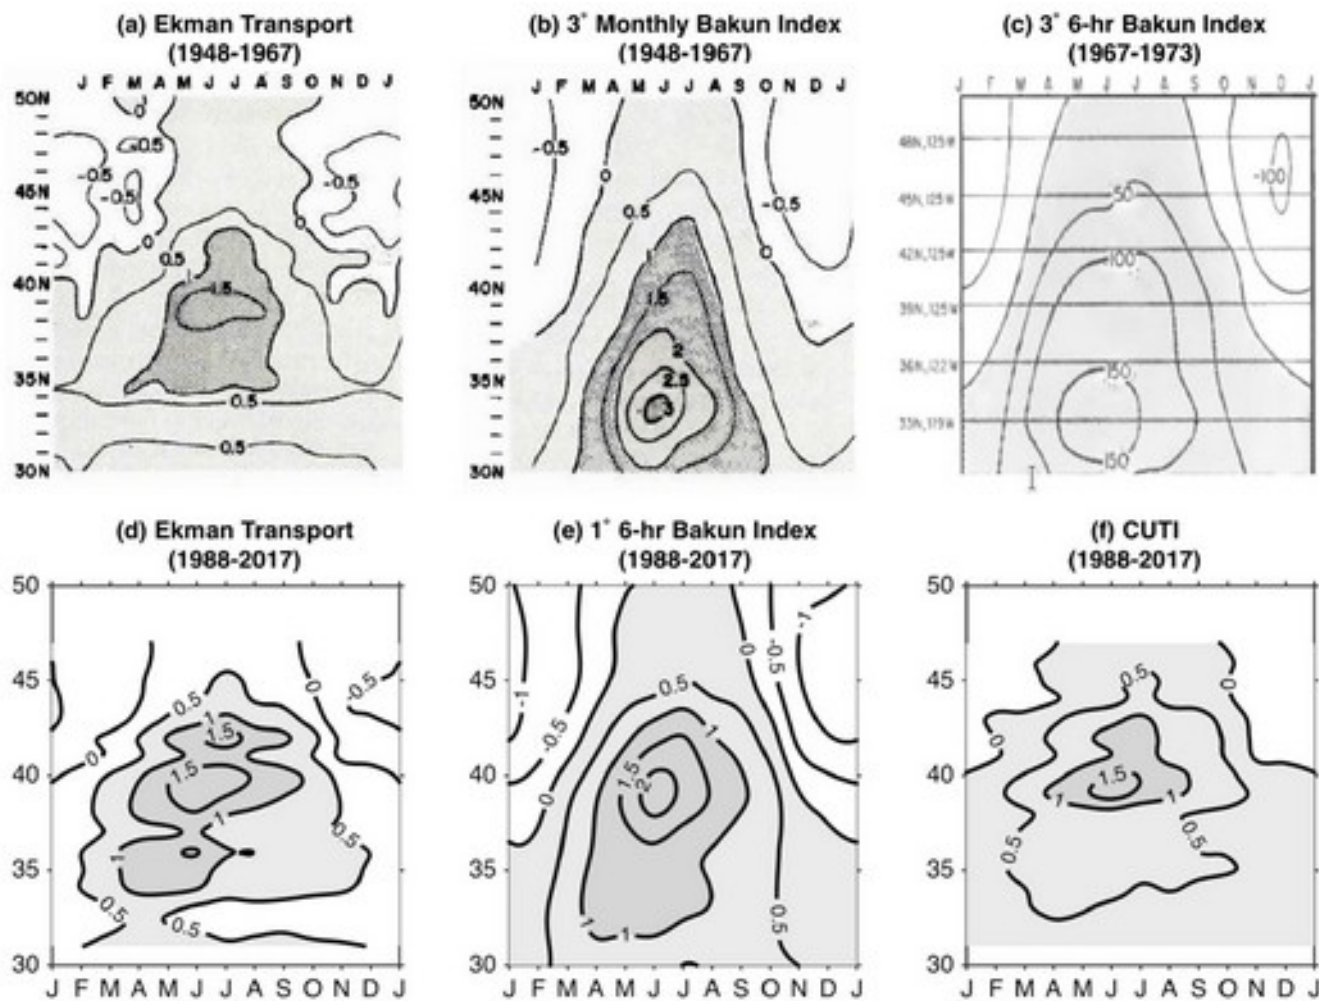

Figure 2. Mean 1988–2017 vertical velocity at the base of the mixed layer during the upwelling season (March–August), obtained from the Regional Ocean Modeling System reanalyses. The 3° Fleet Numerical Meteorology and Oceanography Center sea level pressure grid is overlaid, with filled circles indicating locations used historically for calculation of the Bakun Index. Black lines outline regions of integration for the new upwelling indices.

shelves, with sustained upwelling favorable winds, and in regions of strong stratification (Barton et al., 1977; Estrade et al., 2008; Jacox & Edwards, 2011; Lentz & Chapman, 2004). Similarly, curl-driven upwelling can be important very close to shore, particularly in the lee of capes and headlands where expansion fans in the marine boundary layer occur within tens of kilometers of the coast (Dever et al., 2006; Fiechter et al., 2014; Koračin & Dorman, 2001; Pickett & Paduan, 2003). Furthermore, wind products with higher spatial resolution show the coastal wind drop-off occurring in a narrower coastal band (Capet et al., 2004), increasing the overlap of estimated upwelling due to coastal divergence and wind stress curl. Thus, while upwelling variability near shore is out of phase with upwelling variability farther offshore (Jacox et al., 2014) neither can be attributed solely to coastal divergence or wind stress curl.

3. Revisiting the Bakun Index

The Bakun Index methodology was originally laid out in two technical reports (Bakun, 1973, 1975) that while highly cited are challenging to obtain. A more accessible report by Schwing et al. (1996) also details the Bakun Index calculation, and we review it here. While some of the details of the Bakun Index calculation have changed over time, the methodology has not. Here we present the original calculation described by Bakun (1973) and implemented by NOAA. After this overview we describe changes employed in subsequent iterations of the index.

An estimate of sea level pressure (SLP) is obtained from an operational atmospheric model run by the U.S. Navy's Fleet Numerical Meteorology and Oceanography Center (FNMOC), formerly the Fleet Numerical Weather Center. SLP gradients are then estimated at the grid points corresponding to upwelling index locations (Figure 2) by calculating the pressure difference between grid points on either side and dividing by the distance between them. Because the initial FNMOC grid resolution

“The 1° 6-hr index is best of the three for the post-1996 period when FNMOG has provided SLP fields at 1° resolution”

Figure 3. Climatological transport estimates are plotted against latitude for (top) transport indices as described by Bakun (1973, 1975): (a) Ekman transport estimated from in situ wind measurements (adapted from Bakun, 1973), (b) Bakun Index calculated from monthly 3° sea level pressure (SLP) fields (adapted from Bakun, 1973), (c) Bakun Index calculated from 6-hourly 3° SLP fields (adapted from Bakun, 1975) and (bottom) transport indices calculated 1988–2017: (d) Ekman transport estimated from California Current System Regional Ocean Modelling System reanalysis winds, (e) Bakun Index calculated from 6-hourly 1° SLP fields, (f) revised upwelling index (Coastal Upwelling Transport Index) described herein. Note that panel (c) uses units of m^3/s per 100-m coastline, so values are a factor of 100 greater than in the other panels, which use units of m^3/s per meter coastline (i.e. m^2/s)

In addition to uncertainties in the Ekman transport calculation, the Bakun Index does not (and does not try to) capture several important contributors to upwelling dynamics. First is wind stress curl-driven upwelling associated with alongshore wind gradients (i.e., $d\tau_0^x/dy$ for a coastline oriented in the y -direction), though the Bakun Index does inherently include wind stress curl-driven upwelling associated with zonal gradients in the alongshore wind stress (i.e., $d\tau_0^y/dx$) inshore of the location where the index is calculated. Second is the contribution of the cross-shore geostrophic flow. If the constraint of no horizontal pressure gradient is removed from Ekman theory, equation (1) for the zonal velocity becomes

$$fu = \frac{1}{\rho} \frac{\partial \tau^y}{\partial z} - g \frac{\partial \eta}{\partial y} \quad (6)$$

and equation (2) becomes

$$U^{Ek} + U^{geo} = \frac{\tau_0^y}{\rho f} - \frac{gD}{f} \frac{\partial \eta}{\partial y} \quad (7)$$

where η is the free surface height, g is the gravitational acceleration, and U^{geo} is the zonal geostrophic trans-

4. Improved Upwelling Indices

- The Coastal Upwelling Transport Index (CUTI, pronounced “cutie”), which is comparable to the Bakun Index in that it is an estimate of the total volume of water upwelled or downwelled in a given time period (i.e., the vertical volume flux into or out of the surface layer).
- Second is the Biologically Effective Upwelling Transport Index (BEUTI, pronounced “beauty”), which is an estimate of the total quantity of nitrate upwelled or downwelled in a given time period (i.e., the vertical nitrate flux into or out of the surface layer). BEUTI therefore quantifies not only the intensity of upwelling but also the quality of upwelled waters in terms of their nutrient content, which can strongly influence productivity independent of the surface wind strength (Jacox, Bograd, et al., 2015; Jacox et al., 2016).

Note: here, the ocean state estimates and surface wind forcing are obtained from historical reanalyses of the CCS produced using the Regional Ocean Modeling System (ROMS) with 4-dimensional variational data assimilation.

This method accounts for Ekman transport associated with alongshore wind stress as well as wind stress curl in both the alongshore and cross-shore directions. In contrast, Ekman transport estimated from alongshore wind stress at some offshore location (as in the Bakun Index) omits Ekman suction/pumping associated with alongshore wind stress gradients.

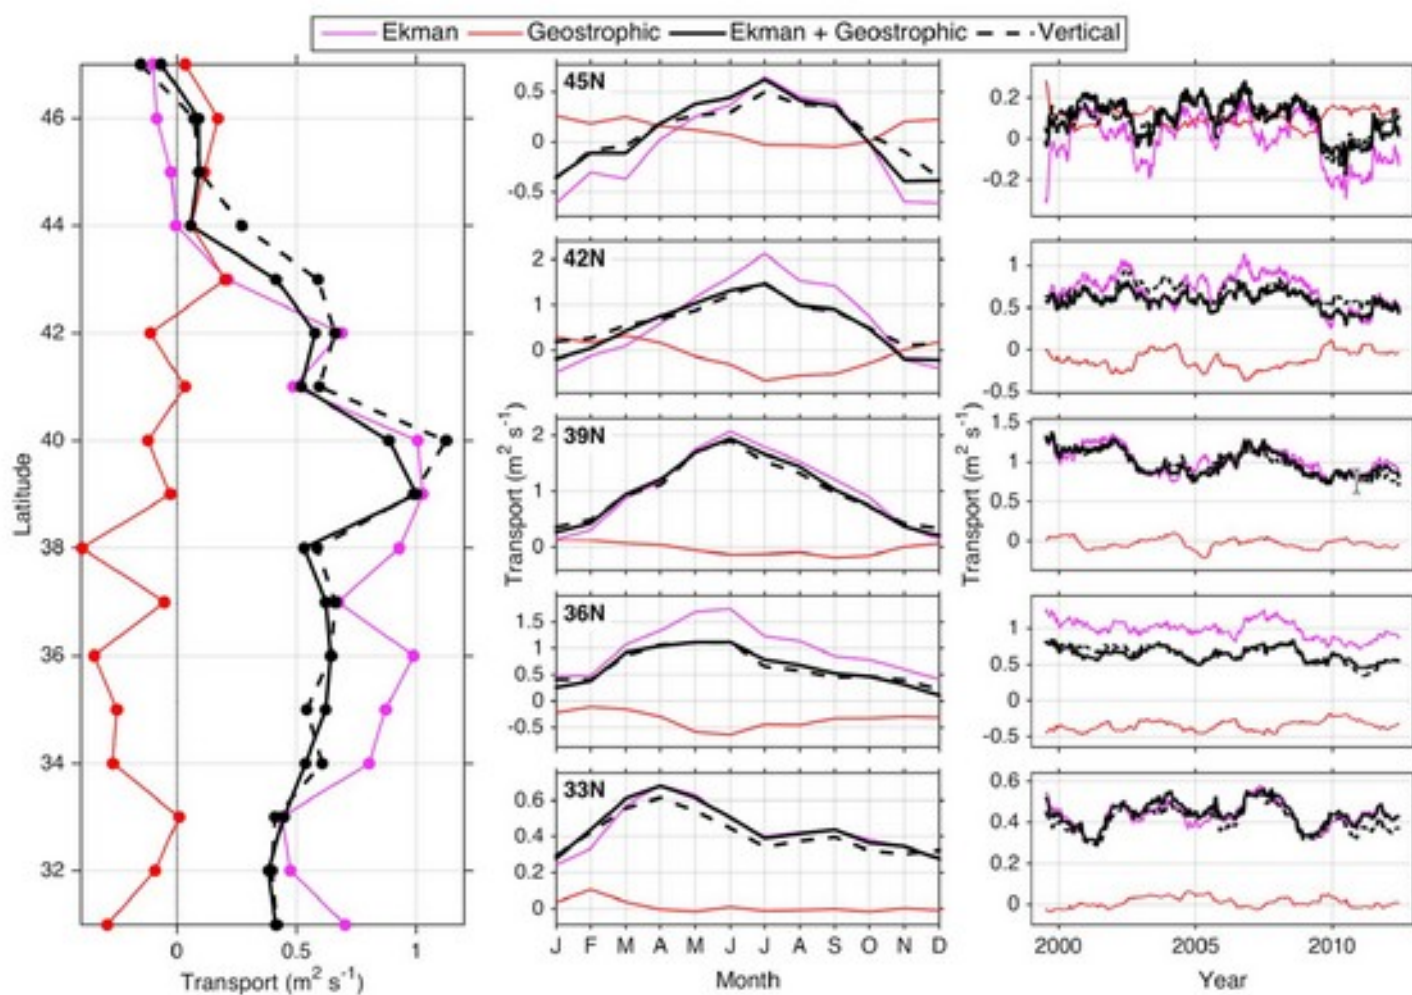

Figure 4. (left) Long-term mean, (middle) seasonal climatology, and (right) interannual variability of transport components, plotted against latitude (left panel) or at select latitudes (middle and right panels). Positive values are upwelling favorable. Transport components were calculated from CCSRA14 for 1999–2012 (see sections 4.1 and 4.2). Interannual variability was calculated by smoothing daily time series with a 12-month running mean. The temporal coverage of the new indices is longer (1988 to present), but they are constructed from multiple reanalyses. Here we focus on a single self-consistent reanalysis to explore individual terms in the transport budget. Note scale differences on y-axes of middle and right panels.

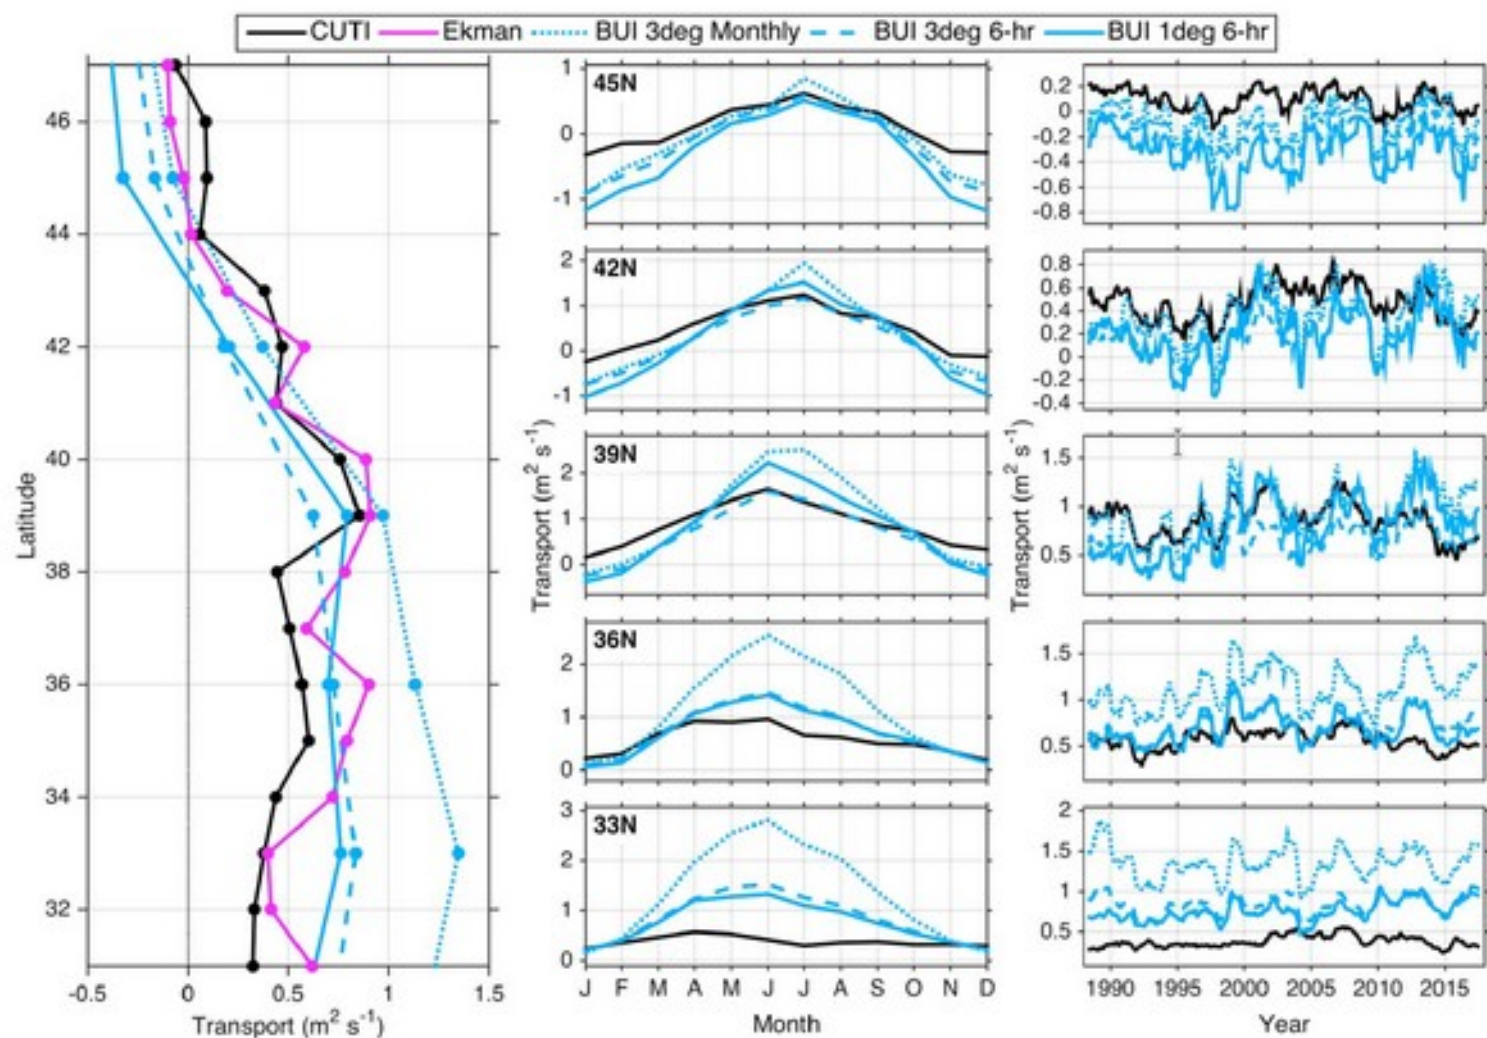

Figure 8. (left) Long-term mean, (middle) seasonal climatology, and (right) interannual variability (12-month running mean) of CUTI and multiple versions of the Bakun Index (BUI), plotted against latitude (left panel) or at select latitudes (middle and right panels). The long-term mean Ekman transport component of CUTI is also plotted for comparison. Indices are shown for 1988–2017. Note scale differences on y-axes of middle and right panels. CUTI = Coastal Upwelling Transport Index.

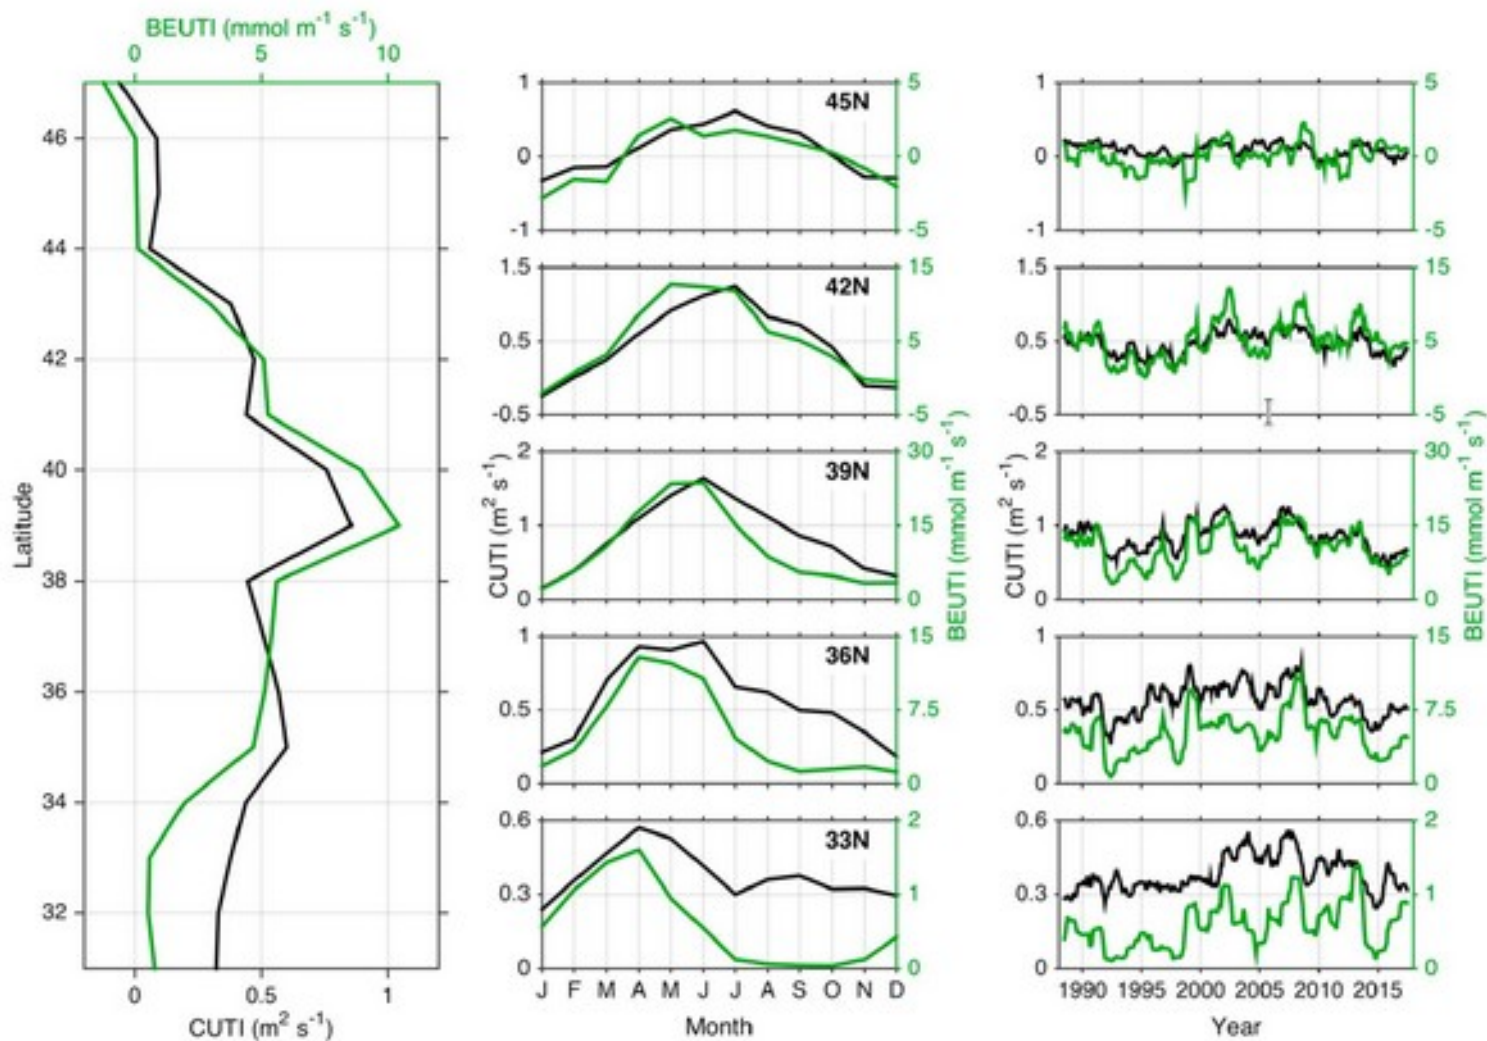

Figure 10. (left) Long-term mean, (middle) seasonal climatology, and (right) interannual variability (12-month running mean) of CUTI and BEUTI, plotted against latitude (left panel) or at select latitudes (middle and right panels). Indices are shown for 1988–2017. Note scale differences on y-axes of middle and right panels. CUTI = Coastal Upwelling Transport Index; BEUTI = Biologically Effective Upwelling Transport Index.

7.2. Creating Similar Indices for Other Regions

A key strength of the Bakun Index is that in theory it can be calculated for any coastline in the global ocean. In regions where the oceanographic model output needed to calculate CUTI or BEUTI are unavailable, SLP (or better yet surface wind stress) from atmospheric reanalyses can be used to estimate upwelling. We suggest calculating Ekman transport as we have here, by integrating along all boundaries of the region of interest rather than rotating winds and estimating offshore transport. Integration around the region of interest eliminates the need for estimating the coastline orientation, ensures that Ekman transport/pumping associated with alongshore and cross-shore variations in the wind are captured, and enables more accurate closure of the transport budget. In regions where high-resolution oceanographic analyses are available, the methodology presented here can be applied to create similar indices.

➔ We must see together what is the best to compute it for the Canary System

6.3. RECENT CHANGES AND TRENDS OF THE UPWELLING INTENSITY IN THE CANARY CURRENT LARGE MARINE ECOSYSTEM

CUISST Index derived from the CMEMS IBI reanalysis data for the 2002–2014 period and from the CMEMS IBI Forecast & Analysis service for the year 2015 (see text for more details on data use). The vertical black line limits the use of both datasets. White horizontal dashed lines denote the latitudes 42°N and 30°N, where CUIEK time series are shown in panels (a) and (b).

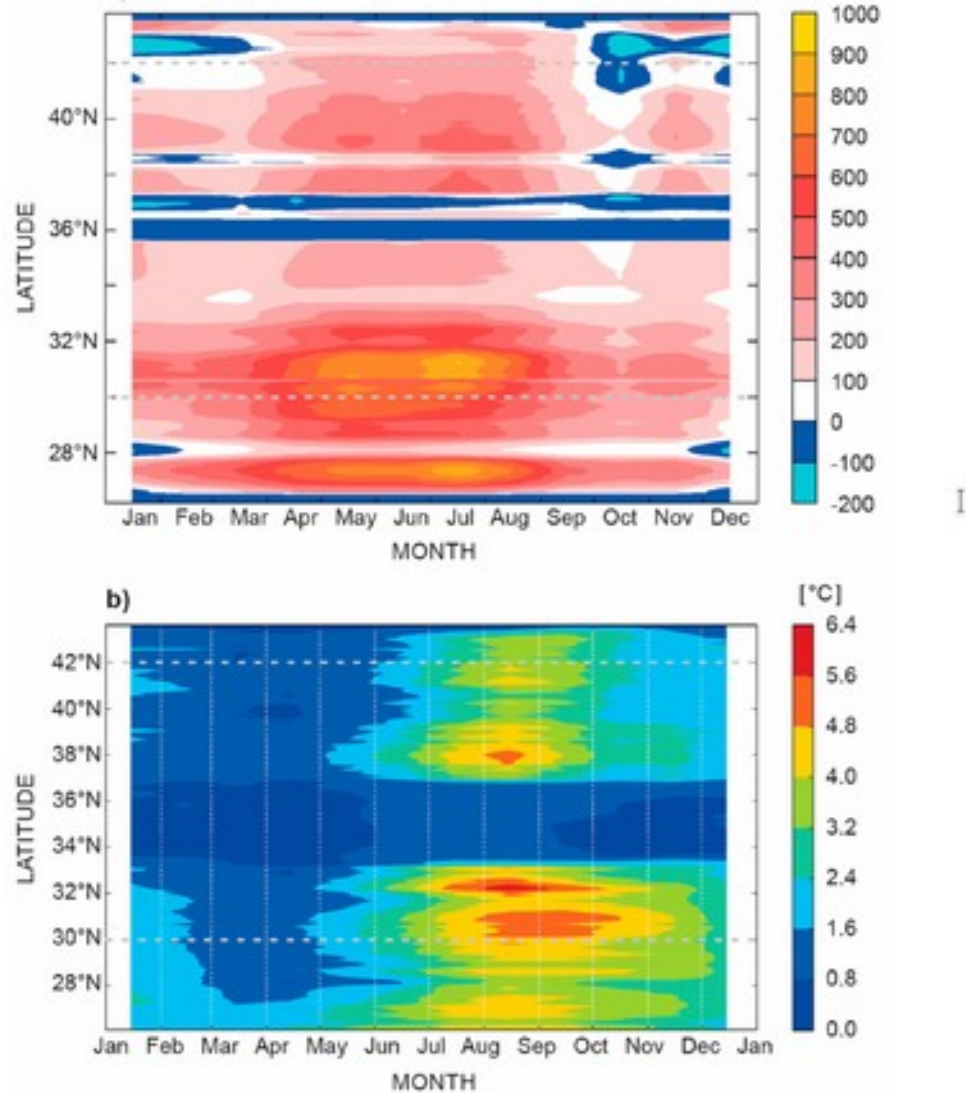

Figure 48. Averaged monthly CULEK (a) and CUISST (b) indexes, contoured by latitude and month. Reference period: 2002–2014 (the CMEMS IBI reanalysis time coverage). Grey horizontal dashed lines denote the latitudes 42°N and 30°N, where CUIEK time series are shown.

Thank you
